\*Corresponding author

Magnesiovesuvianite (IMA 2015-104), ideally  $\text{Ca}_{19}\text{Mg}(\text{Al},\text{Mg})_{12}\text{Si}_{18}\text{O}_{69}(\text{OH})_9$ , a new vesuvianite-group member, was found in an old museum specimen labelled as vesuvianite from the Tuydo combe, near Lojane, Republic of Macedonia. It occurs as radiating aggregates up to 2 cm across consisting of acicular tetragonal crystals (up to 7 mm long and 5–40  $\mu\text{m}$  thick) with distinct fibre-optic effect. Associated minerals are calcite, grossular–andradite and clinocllore. Single crystals of magnesiovesuvianite are transparent, light pink with a silky lustre. Dominant crystal forms are {100}, {110}, {101} and {001}. The Mohs' hardness is 6. The measured and calculated densities are 3.30(3) and 3.35 g/cm<sup>3</sup>, respectively. Mineral is optically uniaxial, negative,  $\omega = 1.725(2)$ ,  $\epsilon = 1.721(2)$ . The chemical composition (wt. % electron-microprobe data) is: SiO<sub>2</sub> 36.73, Al<sub>2</sub>O<sub>3</sub> 20.21, CaO 36.50, MgO 1.80, MnO 0.18, FeO 0.04, Na<sub>2</sub>O 0.01, H<sub>2</sub>O 3.10, total 98.37. The empirical formula based on 19 (Ca + Na) apfu is:  $(\text{Ca}_{18.99}\text{Na}_{0.01})_{\Sigma 19.00}(\text{Mg}_{0.60}\text{Al}_{0.40})_{\Sigma 1.00}(\text{Al}_{11.05}\text{Mg}_{0.70}\text{Mn}_{0.07}\text{Fe}_{0.02})_{\Sigma 11.84}\text{Si}_{17.84}\text{O}_{68.72}(\text{OH})_9$ . Absorption bands in the IR spectrum are: 393, 412, 443, 492, 576, 606, 713, 802, 906, 968, 1024, 3200, 3450, 3630 cm<sup>-1</sup>. The eight strongest lines of the powder X-ray diffraction pattern are (*I*-*d*(Å)-*hkl*): 23–10.96–110, 22–3.46–240, 33–3.038–510, 100–2.740–432, 21–2.583–522, 94–2.365–620, 19–2.192–710, 25–1.6165–672. Magnesiovesuvianite is tetragonal, space group *P4/n*, unit-cell parameters refined from the powder data are *a* 15.5026(3), *c* 11.7858(5), *V* 2832.4(2) Å<sup>3</sup>, *Z* = 2. The crystal structure has been refined to *R*<sub>1</sub> = 0.027 for 3266 unique observed reflections with  $|F_o| \geq 4\sigma_F$ . The structure refinements provided scattering factors of the Y1A,B sites close to 12 *e*<sup>-</sup> that supports predominant occupancy of these sites by the Mg<sup>2+</sup> cations, in perfect agreement with the <sup>27</sup>Al MAS NMR data. Magnesiovesuvianite is a member of the vesuvianite group with Mg<sup>2+</sup> as a dominant cation at the Y1 site. The name magnesiovesuvianite is given to highlight the species-defining role of Mg.

The online version of this article (doi: 10.3190/jgeosci.229) contains supplementary electronic material.

## 1. Introduction

Due to significant chemical variations and the dependence of the symmetry (space group) upon crystallization temperature (Gnos and Armbruster 2006), minerals of the vesuvianite group seem to indicate conditions of formation and, thus, are of practical interest to geology and geochemistry. Perfect acicular vesuvianite crystals and whiskers show pronounced light-conducting properties (Galuskin et al. 2007). Owing to their structural and chemical complexity, vesuvianite-group minerals are also considered as potential components of silicate materials for the immobilization of dangerous waste products incorporating toxic and radio-

active elements such as <sup>222</sup>Rn, <sup>220</sup>Rn or La (Li et al. 2009; Malczewski and Dziurawicz 2015; Tang et al. 2015).

At present the vesuvianite group consists of six minerals: vesuvianite itself  $\text{Ca}_{19}(\text{Al},\text{Mg},\text{Mn},\text{Fe})_{13}\text{Si}_{18}\text{O}_{68}(\text{OH},\text{F},\text{Cl},\text{O})_{10}$  (Werner 1795), wiluite  $\text{Ca}_{19}(\text{Al},\text{Mg},\text{Fe},\text{Ti})_{13}(\text{B},\text{Al},\square)_5\text{Si}_{18}\text{O}_{68}(\text{O},\text{OH})_{11}$  (Groat et al. 1998), fluorvesuvianite  $\text{Ca}_{19}(\text{Al},\text{Mg},\text{Mn},\text{Fe})_{13}\text{Si}_{18}\text{O}_{68}(\text{F},\text{OH})_{10}$  (Britvin et al. 2003), manganvesuvianite  $\text{Ca}_{19}\text{Mn}^{3+}(\text{Al},\text{Mn}^{3+},\text{Fe}^{3+})_{10}(\text{Mg},\text{Mn}^{2+})_2\text{Si}_{18}\text{O}_{69}(\text{OH})_9$  (Armbruster et al. 2002), cyprine  $\text{Ca}_{19}\text{Cu}^{2+}(\text{Al},\text{Mg})_{12}\text{Si}_{18}\text{O}_{69}(\text{OH})_9$  (Panikorovskii et al. in print a) and alumovesuvianite  $\text{Ca}_{19}\text{Al}(\text{Al},\text{Mg})_{12}\text{Si}_{18}\text{O}_{69}(\text{OH})_9$  (Panikorovskii et al. in print b). Taking into account the modular structure,

**Fig. 1a** – A general view of the vesuvianite crystal structure projected along the *c* axis (grossular module highlighted by white circle). **b** – The grossular module in the vesuvianite structure. **c** – Strings of the Y1–X4–X4–Y1 positions in the vesuvianite structure.

hydrogarnet-type substitutions, incorporation of sodium and boron, and different cation coordinations, the general formula of vesuvianite-group minerals can be written as  $X_{16}X_{12}X_4Y_1Y_2Y_3T_{0-5}[(ZO_4)_{10-x}(H_4O_4)_x](Z_2O_7)_4(OH,O)_{10-11}$ , where  $x < 3$ , *X* are seven- to nine-coordinated sites (Ca, Na, K, Fe<sup>2+</sup>, REE), X4 has a square antiprism coordination (Ca, Na), Y1 has a square pyramidal coordination (Fe<sup>3+</sup>, Mg, Al, Fe<sup>2+</sup>, Cu<sup>2+</sup>), Y2 and Y3 have octahedral coordination (Al, Mg, Zn, Fe<sup>2+</sup>, Fe<sup>3+</sup>, Mn<sup>2+</sup>, Mn<sup>3+</sup>, Ti, Cr, Zn), T<sub>0-5</sub> (B, Fe or Al) is the additional site with triangular and tetrahedral coordination, whereas ZO<sub>4</sub> (Si, H<sub>4</sub>O<sub>4</sub>) and Z<sub>2</sub>O<sub>7</sub> are ortho- and diortho- groups, respectively (Warren and Modell 1931; Coda et al. 1970; Dyrek et al. 1992; Groat et al. 1992; Armbruster and Gnos 2000b; Galuskin et al. 2003; Aksenov et al. 2016, Panikorovskii et al. 2016a, b, c).

The crystal structure of vesuvianite-group minerals has a modular character (Fig. 1a) and may be considered as containing one-dimensional grossular modules running along the fourfold axis (Allen and Burnham 1992). The modules are linked by the Si<sub>2</sub>O<sub>7</sub> groups (Fig. 1b); thereby it forms framework with channels occupied by the Y1A,B (Y1) and X4A,B (X4) sites (Fig. 1c) in the Y1A–X4A–X4B–Y1B sequence with the distances smaller than 1.3, 1.3 and 2.5 Å between the Y1A–X4A, Y1A–X4A and X4A–X4B positions, respectively. Various occupancies of Y1A,B and X4A,B positions lead to the different ordering schemes and, as a result, to different space groups (Giuseppetti and Mazzi 1983; Fitzgerald et al. 1986b; Pavese et al. 1998; Armbruster and Gnos 2000a, b).

The majority of vesuvianite samples contain significant amounts of Mg (usually in the range of 0.8–6.7 wt. %), which mostly occupies the octahedrally coordinated Y3

positions (Groat et al. 1992). Single crystal X-ray and EXAFS investigations by Valley et al. (1985) and Ohkawa et al. (1992) demonstrated that Mg predominates in the five-coordinated Y1 site in vesuvianites from Georgetown, California, USA, and Chichibu, Saitama Prefecture, Japan.

In this paper, we report data for magnesiovesuvianite, ideally Ca<sub>19</sub>Mg(Al,Mg)<sub>12</sub>Si<sub>18</sub>O<sub>69</sub>(OH)<sub>9</sub>, a new vesuvianite-group mineral with a predominance of Mg at the Y1A,B sites. Both the new mineral and its name have been approved by the IMA Commission on New Minerals, Nomenclature and Classification (IMA 2015-104).

## 2. Occurrence

Magnesiovesuvianite was found in an old museum specimen from the Tuydo combe, near Lojane, Republic of Macedonia, deposited in the systematic collection of the Fersman Mineralogical Museum of the Russian Academy of Sciences, Moscow, Russia, under catalogue no. 59783 (acquired in 1957). This specimen is considered as the holotype of magnesiovesuvianite.

Associated minerals are calcite, garnet of the grossular–andradite series and clinocllore. The new mineral occurs in cavities of a garnet-bearing rodingite and definitely has a hydrothermal origin.

## 3. General appearance, physical properties and optical data

Magnesiovesuvianite forms radiating aggregates up to 2 cm across consisting of acicular tetragonal crystals

**Fig. 2** Cluster of pink magnesiovesuvianite crystals with fibre-optic effect.

(up to 7 mm long and 5–40  $\mu\text{m}$  thick) with a distinct fibre-optic effect (Fig. 2). This effect is used as a means of transmitting light between the two ends of the fibre, e.g. in computer networking. Crystals are elongated along [001]; the dominant forms are {100} and/or {110}, both usually with striation along [001]; crystals are terminated by the {111} and {101} or {001} faces (Fig. 3). They occur in open cavities or are embedded in fine-grained apple-green garnet.

Magnesiovesuvianite crystals are transparent, light pink, with a silky lustre. Cleavage has not been observed. The Mohs' hardness is 6. The density measured by flotation in diluted Clerici solution ( $D_{\text{meas}}$ ) is 3.30(1)  $\text{g}/\text{cm}^3$  and calculated using the empirical formula ( $D_{\text{calc}}$ ) is 3.35  $\text{g}/\text{cm}^3$ .

The mineral is optically uniaxial, negative,  $\omega = 1.725(2)$ ,  $\epsilon = 1.731(2)$  (in white light); pleochroism is not observed. The Gladstone–Dale compatibility index (Mandarino 1981) is  $-0.018$  (superior) for  $D_{\text{calc}}$  and  $-0.032$  (excellent) if  $D_{\text{meas}}$  is used.

## 4. Chemical composition

### 4.1. Electron microprobe data

Chemical analyses of magnesiovesuvianite (Tab. 1) were obtained by Cameca MS-46 electron microprobe (20 kV, 20–30 nA, beam diameter 10  $\mu\text{m}$ ) and by a HITACHI S-3400N scanning electron microscope equipped with the INCA Wave 500 system (WDS mode; 20 kV; 10 nA; beam diameter 5  $\mu\text{m}$ ). Contents of other elements with the atomic numbers higher than eight were below the detection limits. The  $\text{H}_2\text{O}$  content was analysed by thermogravimetric analysis (TGA). Carbon dioxide and boron were not analysed because of the absence of bands corresponding to the C–O and B–O vibrations in the IR spectrum. The empirical formula of magnesiovesuvianite, calculated on the basis of 19 (Ca + Na) apfu and taking into account the solid-state magic-angle spinning nuclear magnetic resonance (MAS NMR) data, is:  $(\text{Ca}_{18.99}\text{Na}_{0.01})_{\Sigma 19.00}(\text{Mg}_{0.60}\text{Al}_{0.40})_{\Sigma 1.00}(\text{Al}_{11.05}\text{Mg}_{0.70}\text{Mn}_{0.07}\text{Fe}_{0.02})_{\Sigma 11.84}\text{Si}_{17.84}\text{O}_{68.72}(\text{OH})_9$ . The idealized formula is  $\text{Ca}_{19}\text{Mg}(\text{Al},\text{Mg})_{12}\text{Si}_{18}\text{O}_{69}(\text{OH})_9$ , which ideally requires MgO 2.82, CaO 37.13,  $\text{Al}_2\text{O}_3$  19.54,  $\text{SiO}_2$  37.68,  $\text{H}_2\text{O}$  2.83, total 100.00 wt. %.

**Tab. 1** Chemical composition of magnesiovesuvianite (wt. %)

Constituent	Mean	Range	Stand. Dev.	Probe Standard
$\text{SiO}_2$	36.73	36.27–37.35	0.17	$\text{SiO}_2$
$\text{Al}_2\text{O}_3$	20.01	19.52–20.67	0.19	$\text{Al}_2\text{O}_3$
CaO	36.50	35.80–37.17	0.39	$\text{CaCO}_3$
MgO	1.80	1.62–1.99	0.08	MgO

FeO	0.04	0.00–0.23	0.04	Fe
$\text{Na}_2\text{O}$	0.01	0.00–0.15	0.04	NaCl
$\text{H}_2\text{O}$	3.10			
Total	98.37	96.68–99.33		

**Fig. 3** Back scattered-electron image of two types of acicular crystals of magnesiovesuvianite.

Fig. 4 Thermogravimetric (wt. %, green line) and differential scanning calorimetry (blue line) curves of magnesiovesuvianite.

#### 4.2. Thermogravimetric analyses and differential scanning calorimetry (TGA/DSC)

This study was performed using a NETZSCH STA 449 F3 Jupiter thermoanalyzer in a dynamic argon atmosphere (heating rate: 10 °C/min, with aluminium oxide standard, sample mass 66.6 mg and temperature range from the room temperature to 1100 °C).

The TGA and DSC curves (Fig. 4) of magnesiovesuvianite have one major step of weight loss, which corresponds to an endothermic effect at 1024 °C and can be assigned to the dehydroxylation process (Földvari 2011). The TGA and DSC curves of magnesiovesuvianite correspond to low-symmetry vesuvianite ( $P4/n$  or  $P4nc$ ), which usually has a one-step weight loss with a sharp endothermic peak in the temperature range of 820–1090 °C (Żabiński et al. 1996). Total weight loss for magnesiovesuvianite is

Fig. 5a –  $^{27}\text{Al}$  MAS NMR spectrum of magnesiovesuvianite. b –  $^1\text{H}$  MAS NMR spectrum of magnesiovesuvianite.

Al (<sup>V</sup>Al). It is assigned to Al at the Y2(A,B) and Y3(A,B) sites. At the same time the weak peak at 39.41 ppm should be assigned to Al at the 5-coordinated Y1(A,B) site. Integral intensities of these peaks are 96.5 to 4.5

## 5. Spectroscopic studies

### 5.1. Solid-state magic-angle spinning nuclear magnetic resonance (MAS NMR)

#### 5.1.1. <sup>27</sup>Al MAS NMR study

The <sup>27</sup>Al NMR spectrum was obtained at room temperature by means of a Bruker Advance III 400 WB spectrometer at 104.24 MHz. The MAS spin rate of the rotor was 20 kHz. For these investigations a single-pulse sequence was used with a pulse length of 86 kHz, with recycle delay 1 s and number of scans 4096.

The NMR spectrum (Fig. 5a) of magnesiovesuvianite contains two peaks centred at -3.29 ppm and 39.41 ppm. The peak at -3.29 ppm is in the range of chemical shifts for octahedrally coordinated

Largest diff. peak/hole (e Å <sup>-3</sup> )	0.50/-0.48

%. The broad symmetric peaks observed at  $\pm 190$  ppm belong to spinning sidebands. It should be noted that very similar data have been reported by Phillips et al. (1987) and Olejniczak and Źabiński (1996), who pointed out that the  $^{27}\text{Al}$  MAS NMR spectra for vesuvianites from Asbestos, Canada, and Piz Lunghin, Switzerland, contain two lines corresponding to  $^{\text{V}}\text{Al}$  and  $^{\text{VI}}\text{Al}$ .

### 5.1.2. $^1\text{H}$ MAS NMR study

The  $^1\text{H}$  NMR spectrum was obtained at room temperature using a Bruker Advance III 400 WB spectrometer operating at 400.23 MHz. The MAS spin rate of the rotor was 20 kHz. A single-pulse sequence was used with a pulse length of 100 kHz, recycle delay of 20 s and 32 scans.

The  $^1\text{H}$  MAS NMR spectrum (Fig. 5b) of magnesiovesuvianite contains two peaks centred at 6.52 and  $-0.95$  ppm in contrast to the spectrum of ‘hydrovesuvianite’, which contains three peaks centred at 6.74, 3.38 and  $-0.95$  ppm (Panikorovskii et al. 2016c). Absence of the peak at 3.38 ppm indicates the insignificant role of a hydrogarnet  $\text{SiO}_4^{4-} \leftrightarrow [\text{H}_4\text{O}_4]^{4+}$  substitution in magnesiovesuvianite. The O–H $\cdots$ O distances calculated using the formula  $\delta_{\text{iso}}$  (ppm) =  $79.05 - 0.255d$  (O–H $\cdots$ O) (pm) (Yesinowski et al. 1988) are 2.84 and 3.13 Å. The most intense peak at 6.74 ppm corresponds to the chemical shifts of the O(11)–H(1a)–O(7) and the O(10)–H(2)–O(10) bonds that is in agreement with the distances of 2.784(4) Å and 2.74–2.82 Å, respectively, reported for

vesuvianites by many authors (Lager et al. 1999; Ohkawa et al. 1992, 1994, 2009; Pavese et al. 1998; Armbruster and Gnos 2000c; Galuskin 2005). The peak at  $-0.95$  ppm can be attributed to the O(11)–H(1b)–O(11) bond, since its chemical shift agrees with the distances of 3.01–3.04 Å (Pavese et al. 1998; Lager et al. 1999).

### 5.2. Infrared spectroscopy

The infrared spectrum of magnesiovesuvianite was obtained using a Bruker Vertex 70 IR spectrometer at room temperature (KBr pellet, resolution  $4\text{ cm}^{-1}$ ). In the IR spectrum (Fig. 6), the absorption bands at 393, 412 and  $492\text{ cm}^{-1}$  belong to the  $[\text{Al–O}]_6$  stretching vibrations. The  $443\text{ cm}^{-1}$  band corresponds to the  $\nu_2$  symmetric bending vibrations of the Si–O bonds. The bands at 576 and  $606\text{ cm}^{-1}$  correspond to the  $\nu_4$  asymmetric bending vibrations of the Si–O bonds. A weak band at  $713\text{ cm}^{-1}$  may be assigned to vibrations of hydroxyl groups. The bands at 802, 906 (doublet), 968 and  $1024\text{ cm}^{-1}$  may be assigned to asymmetric stretching vibrations of Si–O and Si–O–Si bonds. The presence of a doublet with equal intensities of its components ( $576$  and  $606\text{ cm}^{-1}$ ) corresponding to the  $\nu_4$  asymmetric bending vibrations is in agreement with the  $P4/n$  symmetry (Kurazhkovskaya et al. 2003).

The bands in the range  $3200\text{--}3630\text{ cm}^{-1}$  correspond to O–H stretching vibrations. A band with a maximum at  $3630\text{ cm}^{-1}$  in the spectrum of magnesiovesuvianite thus corresponds to the band B ( $3635$ )-type. A broad band at  $3450\text{ cm}^{-1}$  may belong to the F ( $3487$ ) and G ( $3430$ ) bands, which corresponds to the Mg–Al–F and  $\text{Fe}^{2+}$ –Al–F local configurations of O(11)H site belonging to the trimer of edge-sharing octahedra  $Y2\text{--}Y3\text{--}Y2$  and this assignment is unlikely due to the absence of F and the low Fe content. The shoulder at  $3200\text{ cm}^{-1}$  corresponds to the J ( $3210$ ) band (O(10)–H stretching vibrations) (Groat et al. 1995) or JK band (Bellatrecchia et al. 2005). As shown by Kurazhkovskaya et al. (2003) with Borovikova and Kurazhkovskaya (2006), the presence of the strong band at  $3630\text{ cm}^{-1}$  is characteristic of the ‘low’ vesuvianites, whereas ‘high’ vesuvianites show a strong band at  $3560\text{ cm}^{-1}$ .

Fig. 6 Infrared spectrum of magnesiovesuvianite.

## 6. X-ray crystallography

### 6.1. Powder X-ray diffraction data

Powder X-ray diffraction data (Tab. 2) were collected by a Bruker Phazer D2 diffractometer in the  $2\theta$  range of  $5\text{--}80^\circ$  ( $\text{CuK}\alpha$ ;  $1.5418 \text{ \AA}$ ) with scanning steps of  $0.02^\circ$  in  $2\theta$ . The normal-focus Cu X-ray tube was operated at 40 kV and 30 mA. The unit-cell dimensions determined from the corrected X-ray powder-diffraction by Rietveld refinement using the Topas program (Bruker AXS 2009) are as follows:  $a = 15.5026(3) \text{ \AA}$ ,  $c = 11.7856(5) \text{ \AA}$ ,  $V = 2832.4(2) \text{ \AA}^3$ .

### 6.2. Crystal-structure refinement

The single-crystal X-ray diffraction experiment was carried out using an Agilent Technologies Xcalibur Eos diffractometer operated at 50 kV and 40 mA. A hemisphere of three-dimensional data was collected at room temperature using monochromatic  $\text{MoK}\alpha$  X-radiation with frame widths of  $1^\circ$  and 80 s count for each frame. For the investigated sample, 208  $0kl$  and  $hhl$  reflections were observed that violated the  $k + l \neq 2n$  and  $l \neq 2n$  absence conditions, indicative of the low symmetry of the crystal structure (Armbruster and Gnos 2000b). Other 14 observed reflections belonged to the  $hk0$  family with  $h + k \neq 2n$ . The observed systematic absences are consistent with the space group  $P4/n$ . Attempts to refine the crystal structure in the  $P4nc$  space group led to a large number of atoms with physically unrealistic anisotropic displacement parameters.

The crystal structure was refined using a merohedral twin model (2-fold axis along  $[110]$ ) with the twin ratio  $0.485/0.515$  to  $R_1 = 0.027$  for 3266 unique observed reflections with  $|F_o| \geq 4\sigma_F$  using the *SHELX* program (Sheldrick 2008). Empirical absorption correction was applied

The refined crystal chemical formula is:

in the CrysAlisPro (Agilent Technologies 2014) program using spherical harmonics, implemented in the SCALE3 ABSPACK scaling algorithm. Volumes of coordination polyhedra were calculated using the VESTA 3 program (Momma and Izumi 2011).

Experimental details and crystallographic parameters are given in Tab. 3. The final atomic coordinates and isotropic displacement parameters are in Tab. 4, selected interatomic distances in Tab. 5 and anisotropic displacement parameters in Tab. 6.

X2A–O5B	2.423(3)		X4A–O9	2.585(3)	<Y1B–O>	2.002	

The tetrahedral Z1A,B; Z2A,B and Z3A,B positions in the crystal structure of magnesiovesuvianite are occupied by Si atoms only. The Z1A,B sites demonstrate small Si deficiencies. Both have slightly increased <Z1A–O> and <Z1B–O> distances of 1.647 and 1.666 Å, respectively, and the mean electron counts are 13.3 and 12.3 electrons per formula unit (*epfu*) (for the Z1A and Z1B positions, respectively) in agreement with the  $\text{SiO}_4^{4-} \leftrightarrow [\text{H}_4\text{O}_4]^{4+}$  substitution (Galuskin 2005), which, however, is insufficient to have any influence upon the  $^1\text{H}$  MAS NMR spectra.

The 7–9 coordinated X1, X2A,B, X3A,B and X4A,B sites are fully populated by Ca atoms only. The site occupancies of the eightfold coordinated X4A and X4B sites in the structure channels (Fig. 1c) are 0.73 and 0.27, respectively.

The principal sites for the identification of magnesiovesuvianite as a new mineral species are the Y1A,B sites (Fig. 7) with a square-pyramidal coordination, where Mg prevails over Al. The average <Y1A–O> and <Y1B–O> bond lengths are 2.140 and 2.002 Å, respectively, which is in agreement with the refined site populations of  $\text{Mg}_{0.19}\text{Al}_{0.08}$  and  $\text{Mg}_{0.41}\text{Al}_{0.32}$ , respectively. The site-scattering factor (*s.s.f.*) for the Y1 site is 11.55 *epfu* (the calculated value is 12.40 *epfu*), in agreement with the occupancy of the Y1A,B sites by Mg only. Considering the MAS-NMR data, the total occupancy of the Y1 site requires  $(\text{Mg}_{0.60}\text{Al}_{0.40})_{\Sigma 1.00}$ . The Y2A and Y2B sites are fully occupied by Al, in agreement with the average <Y2A–O> and <Y2B–O> bond lengths of 1.904 and 1.898 Å, respectively. The average <Y3A–O> and <Y3B–O> bond lengths

The anisotropic displacement factor exponent takes the form:  $-2\pi^2[h^2a \times U_{11} + 2hka \times b \times U_{12} + \dots]$

are 1.953 and 1.932  $\text{\AA}$ , and the calculated occupancy of the Y3A and Y3B sites are  $(\text{Al}_{0.86}\text{Mg}_{0.125}\text{Mn}_{0.015})_{\Sigma 1.00}$  and  $(\text{Al}_{0.905}\text{Mg}_{0.09}\text{Fe}_{0.005})_{\Sigma 1.00}$ , respectively.

The total crystal-chemical formula for magnesiovesuvianite determined on the basis of crystal-structure refinement and taking account the MAS NMR data can be written as:  $(\text{Ca})_{\Sigma 2.00}^{\text{X1}}(\text{Ca})_{\Sigma 2.00}^{\text{X2A}}(\text{Ca})_{\Sigma 4.00}^{\text{X2B}}(\text{Ca})_{\Sigma 4.00}^{\text{X3A}}(\text{Ca})_{\Sigma 4.00}^{\text{X3B}}(\text{Ca})_{\Sigma 0.73}^{\text{X4A}}(\text{Ca})_{\Sigma 0.27}^{\text{X4B}}(\text{Mg})_{\Sigma 0.19}^{\text{Y1A}}(\text{Mg})_{\Sigma 0.27}^{\text{Y1B}}(\text{Al})_{\Sigma 2.00}^{\text{Y2A}}(\text{Al})_{\Sigma 2.00}^{\text{Y2B}}(\text{Al})_{\Sigma 2.00}^{\text{Y3A}}(\text{Mg})_{\Sigma 0.36}^{\text{Y3B}}(\text{Fe})_{\Sigma 0.02}^{\text{Z1A}}(\text{Si})_{\Sigma 0.88}^{\text{Z1B}}(\text{Si})_{\Sigma 1.00}^{\text{Z2A}}(\text{Si})_{\Sigma 4.00}^{\text{Z2B}}(\text{Si})_{\Sigma 4.00}^{\text{Z3A}}(\text{Si})_{\Sigma 4.00}^{\text{Z3B}}(\text{O})_{\Sigma 68.00}(\text{OH})_{\Sigma 8.46}(\text{O})_{\Sigma 1.54}^{\text{O10}}$

## 7. Discussion

There have been several literature reports on Fe-poor vesuvianites, where the content of FeO or  $\text{Fe}_2\text{O}_3$  did not exceed 1 wt. % (Fitzgerald et al. 1986a, b; Phillips et al. 1987; Groat et al. 1992; Ohkawa et al. 1992; Kurazhkovskaya et al. 2003). According to Hoisch (1985), Groat et al. (1992), Ohkawa et al. (1992), and the present work, vesuvianite incorporates Mg at both octahedral Y3A,B and five-coordinated Y1A,B positions for structural stability reasons.

It should be noted that, in the crystal structure of vesuvianite, the Y1A,B sites are usually occupied by  $\text{Fe}^{3+}$

**Fig. 7** The mean of  $\langle Y1-O \rangle$  vs. occupancy diagram for the  $Fe^{3+}$  (blue circles) according to Pavese et al. (1998), Elmi et al. (2011) and Panikorovskii et al. (2016a). Data of present work (green square) and theoretical mean of the 5-coordinated  $Fe^{3+}$  according to Shannon (1976) (red square) are also shown.

(Giuseppetti and Mazzi 1983; Panikorovskii et al. 2016a). In Fe-free vesuvianites, the Y1A,B sites are occupied by Mg and Al. Their proportion probably depends upon the  $\langle Y1-O \rangle$  distance required to stabilize the structure, which is in perfect agreement with compatible  $\langle Fe^{3+}-O \rangle$  distance for the most populated Y1A site (Fig. 7).

The most plausible explanation for the occurrence of magnesiovesuvianite (i.e. the incorporation of Mg at the Y1 sites) is the absence of significant amount of Fe in the crystallization environment of the mineral. Indeed, the observed striation on the prism faces along [001] is typical of the low-temperature  $P4/n$  vesuvianites of a hydrothermal origin (Armbruster et al. 2002; Gnos and Armbruster 2006). Difference between polyhedral volumes (Tab. 7) of pairs Y1A and Y1B (7.1179 and 5.8931 Å<sup>3</sup>), and X4A and X4B (24.8468 and 23.8995 Å<sup>3</sup>) non-equivalent sites (equivalent in  $P4/nnc$  model) agrees with  $P4/n$  symmetry and low temperature of crystallization magnesiovesuvianite. Therefore, it seems likely that the formation of magnesiovesuvianite was the result of com-

**Tab. 7** Data of polyhedral volumes in the crystal structure of magnesiovesuvianite

Polyhedron	Vol. (Å <sup>3</sup> )	Polyhedron	Vol. (Å <sup>3</sup> )
Z1A	2.2747	Y3A	9.8419
Z1B	2.3605	Y3B	9.5162
Z2A	2.2973	X1	24.4433
Z2B	2.2606	X2A	24.5377
Z3A	2.2610	X2B	24.6638
Z3B	2.2035	X3A	32.8596
Y1A	7.1179	X3B	33.0193
Y1B	5.8931	X4A	24.8468
Y2A	9.1105	X4B	23.8995
Y2B	9.0159		

ination of two factors: the relatively high Mg content with the deficit of Fe in the mineral-forming environment from which the mineral crystallized and  $P-T$  conditions of mineral formation.

**Acknowledgements.** This work was supported by the internal SPbU grant 3.38.136.2014 and the President of Russian Federation Grant for leading scientific schools (no. NSh-10005.2016.5). Experimental studies were carried out using resources of the X-ray Diffraction Centre and Geo Environmental Centre “Geomodel” of Saint-Petersburg State University. Nikita V. Chukanov, Lee A. Groat, an anonymous referee, handling editor Jiří Sejkora and editor-in-chief Vojtěch Janoušek are thanked for critical reviews and helpful comments. The authors are grateful to Gregory Yu. Ivanyuk for the photograph of the magnesiovesuvianite specimen.

**Electronic supplementary material.** Supplementary crystallographic data for this paper are available online at the Journal web site (<http://dx.doi.org/10.3190/jgeosci.229>).
